Dr Chris Brauer

A few simple (but relevant) distinctions* and observations

Adaptation:
A feature of an organism that serves a purpose in a given environment and is the result of natural selection *in the past*

Natural selection in progress:
Gene frequencies *changing now* because how different individuals interact with their environment

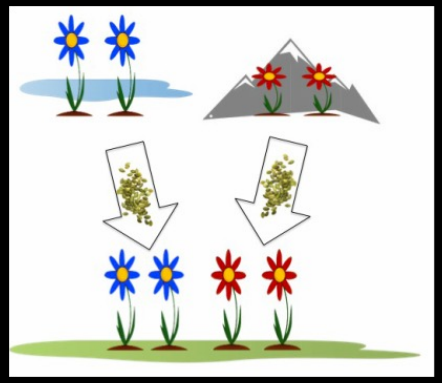
"Selection has nothing to do with what is adequate, or not, for continued survival"

* Modified from:
George C Williams (1966) *Adaptation and Natural Selection*

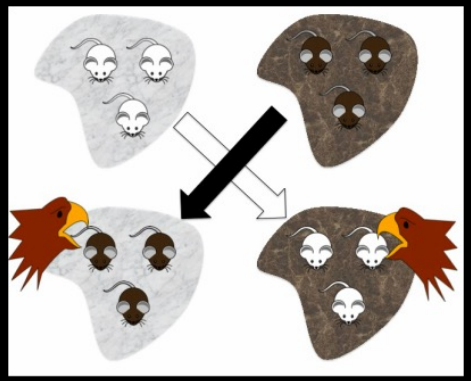
Study (& career?) goals: Explaining adaptations *versus* identifying the signal of selection in progress

Importance of natural history: Understanding spatial non-random mating (i.e. population structure), demographic history and ecology of the study species is key to study natural selection in wild populations

‘Traditional’ ways to study adaptation and natural selection
(without being able to identify its genetic basis)

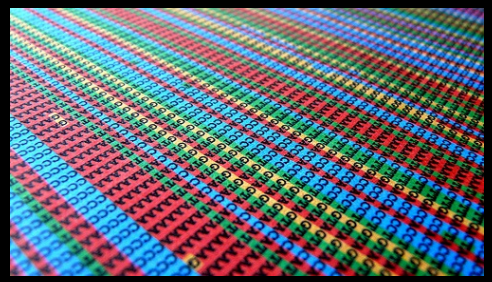


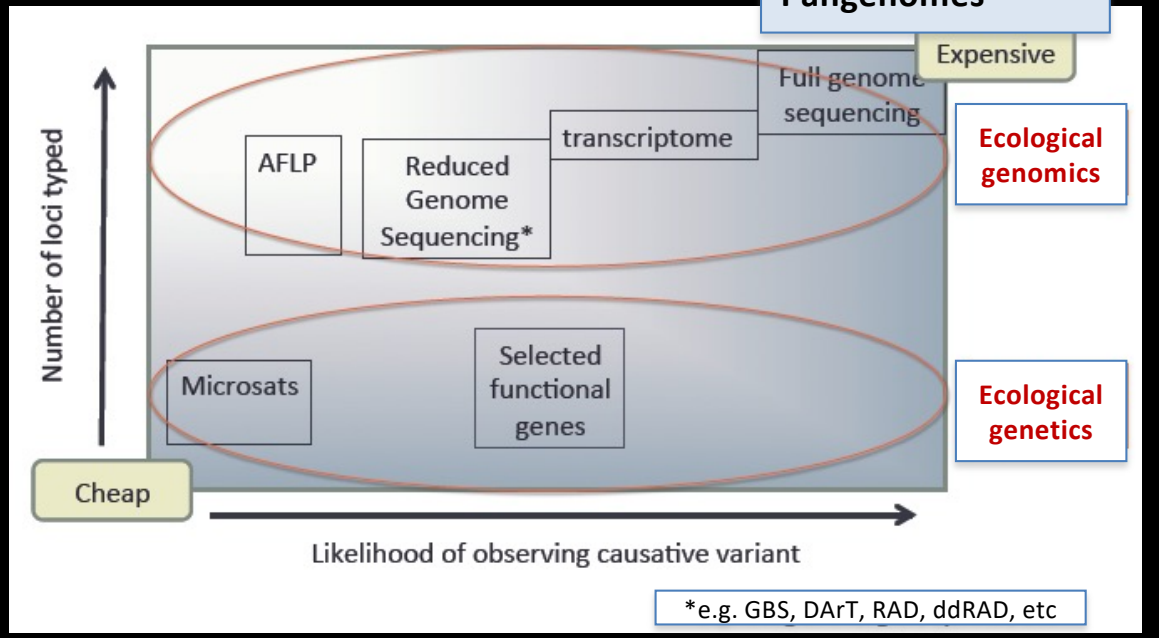
Common garden experiments



Reciprocal transplant experiments

The Era of Genomics





Modified from: Sork (2012) Mol Ecol Symposium, Ottawa

Is reduced-representation sequencing enough?

COMMENT

Unbroken: RADseq remains a powerful tool for understanding the genetics of adaptation in natural populations

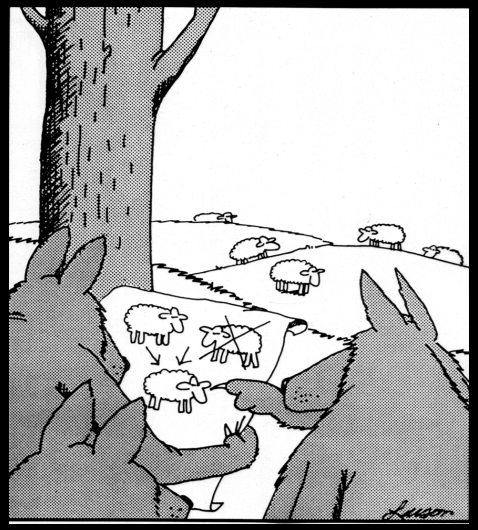
JULIAN M. CATCHEN,* PAUL A. HOHENLOHE,† LOUIS BERNATCHEZ,‡ W. CHRIS FUNK,§
KIMBERLY R. ANDREWS¶ and FRED W. ALLENDORF**

Results should be presented in the context of the experimental characteristics known about the system (including extent of LD) and study conclusions tempered based on their power to detect effects

Random events

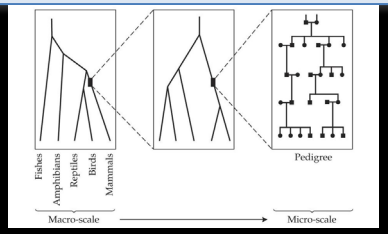
EVOLUTION

Natural selection (non-random)



STANDING GENOMIC VARIATION IN POPULATIONS

NEUTRAL VARIATION
- genome-wide signal
- no impact on fitness

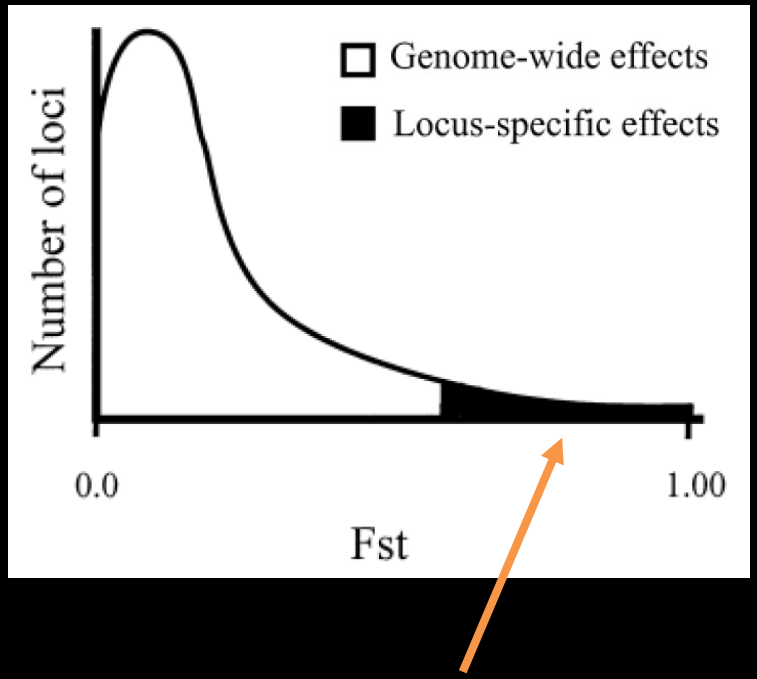


ADAPTIVE VARIATION
- no genome wide signal
- impacts on fitness

Phenotypic plasticity (this can become adaptive)

Identifying natural selection: Outlier tests

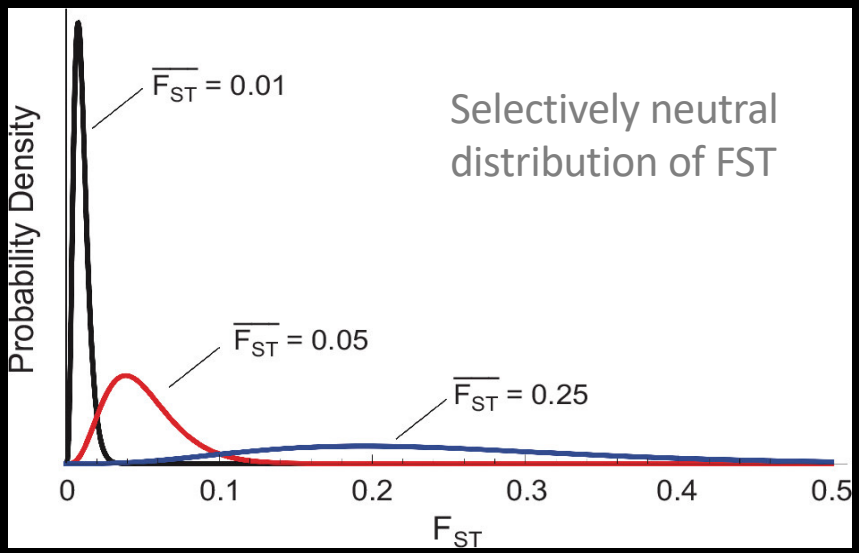
- Frequencies of many alleles often vary across populations due to genome-wide demographic effects = 'neutral' SNPs
- Frequencies of some alleles might co-vary with fitness traits or with environmental variation due to natural selection = 'adaptive SNPs'



Loci with exceptionally high Fst values are 'outlier loci' and *might* represent adaptive loci

Black *et al.* (2001) *Annu. Rev. Entomol.*

Pitfall: difficult test for highly differentiated populations



Hoban *et al.* (2016) *American Naturalist*

Landscape Genomics:

The study of genome-wide neutral and adaptive variation of ecologically diverse populations sampled across heterogeneous landscapes

INVITED REVIEWS AND SYNTHESES

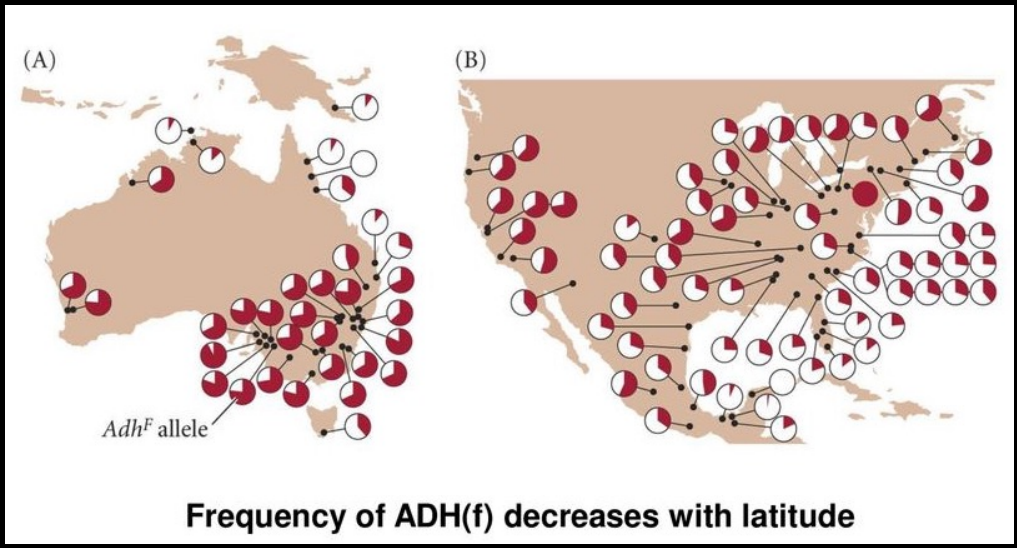
A practical guide to environmental association analysis in landscape genomics

Identifying natural selection: Genotype-Environment Association (GEA) tests

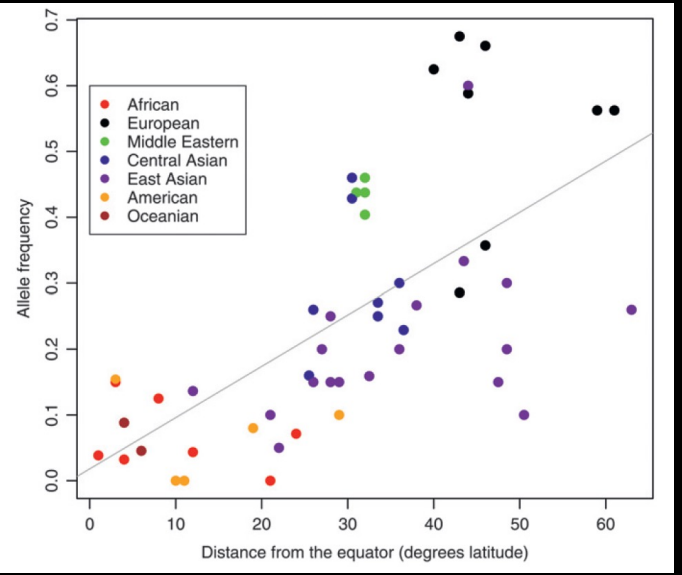
- Strong divergent selection between geographic locations >> local adaptation / differences in average phenotype >> differences in allele frequencies can be maintained in the face of gene flow

GEA tests: Identify candidate adaptive SNPs by testing for direct associations between variation in allele frequencies of each SNP and environmental predictors over the landscape

Pitfall:
non-independence of populations
(shared histories and environments)



Oakeshott *et al.* (1982) *Evolution*



Thompson *et al.* (2004) *Am. J. Hum. Genet*

Identifying natural selection:
Genotype-Environment Association (GEA) tests

Redundancy analysis (RDA) models linear combinations of the explanatory variables (environmental predictors) that explain linear combinations of the response variables (SNPs) >> identify covarying SNPs associated with the multivariate predictors

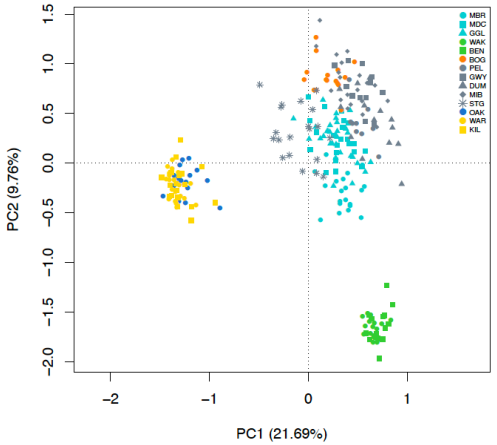
Multivariate ordination

Two major types

Unconstrained

Identifies axes that account for variation in the data e.g. PCA, CA



Constrained

Combines unconstrained ordination with regression analysis, with the axes of variation being constrained to linear combinations of a set of predictor variables e.g. CCA, RDA

Coding in R: the following examples are how I do it, **not** how you should do it…

Use whatever works…
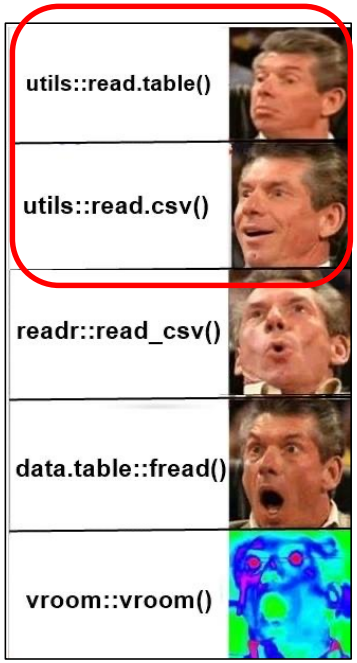
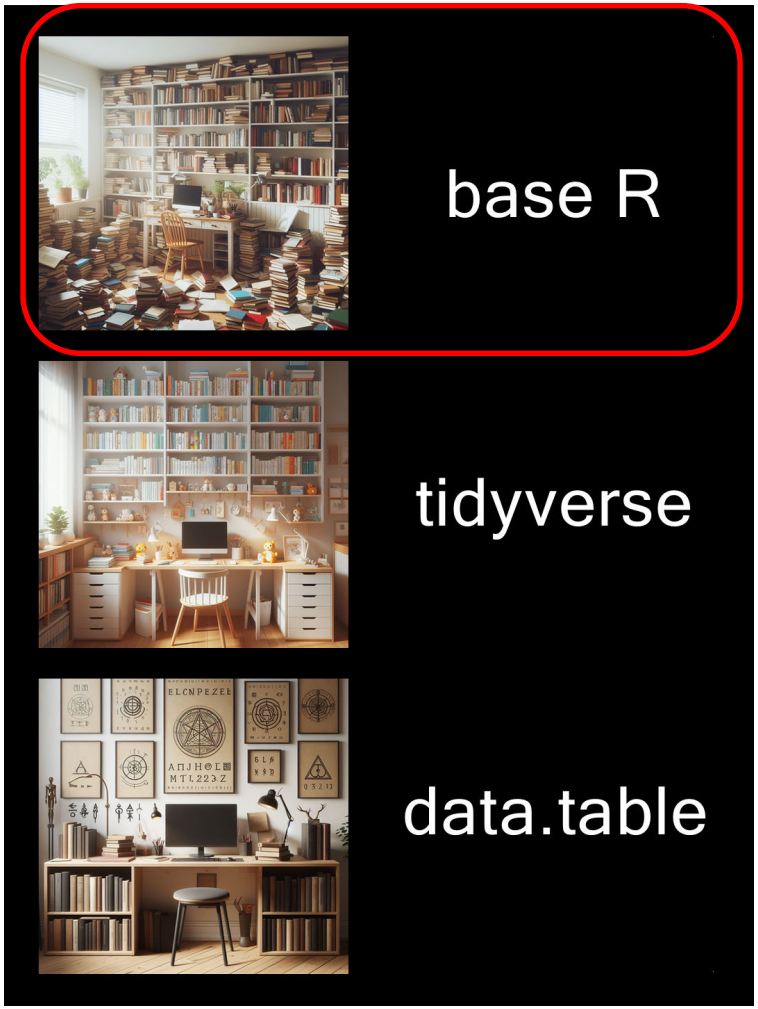
For me that (mostly) looks like this



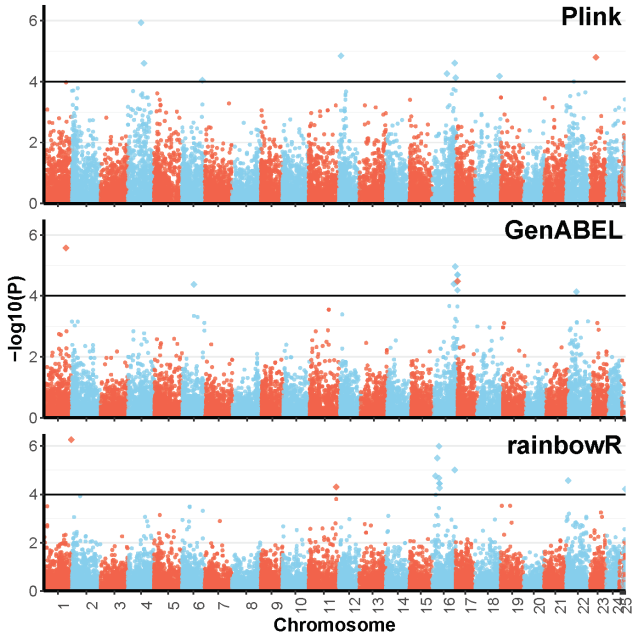


Genome-wide association study (GWAS)

Jonathan Sandoval Flinders University, MELFU

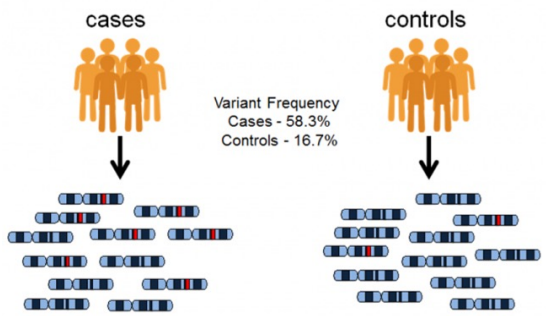
GWAS tests for association between genotypes and phenotypic traits, including diseases, physical characteristics, behavioural traits, and responses to environmental stimuli.

They are important tools to understand biological mechanisms underlying phenotypes, and ultimately to predicting phenotypes from genomic information.



Genome-wide association study (GWAS)

GWAS involves genotyping a large number of genetic markers across the genome several individuals.



Covariate factors that should be considered:

Population structure
Relatedness
Sex bias
Age bias

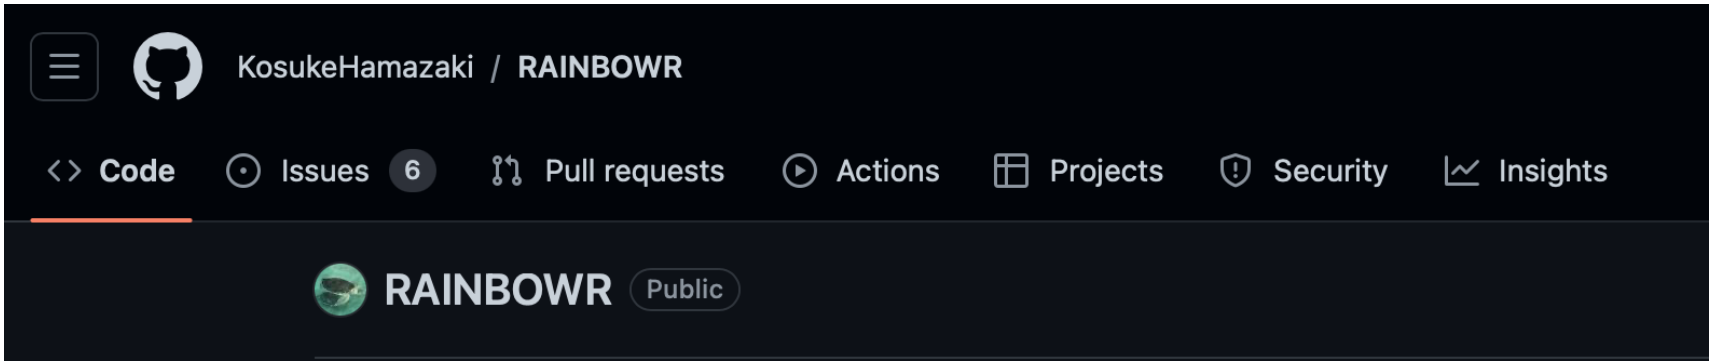
Tune Machine Learning Algorithms in R (random forest case study)

by **Jason Brownlee** on July 31, 2020 in **R Machine Learning**

158



RandomForest

Supervised learning machine algorithm consists of a collection of regression or classification (decision) trees.

It is a versatile and powerful tool:

GEA, GWAS, Genetic offset / ”vulnerability”

Benefits

Lower risk of overfitting
Flexibility (diversity of data and hypotheses)
Easy to determine important features (genes and environmental variables)

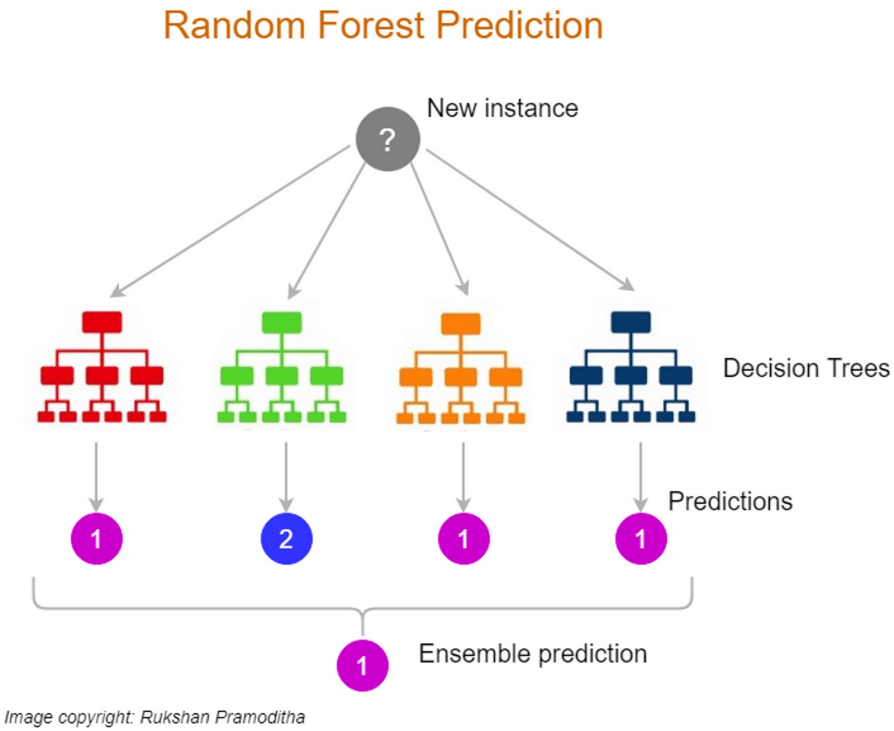


Image copyright: Rukshan Pramoditha

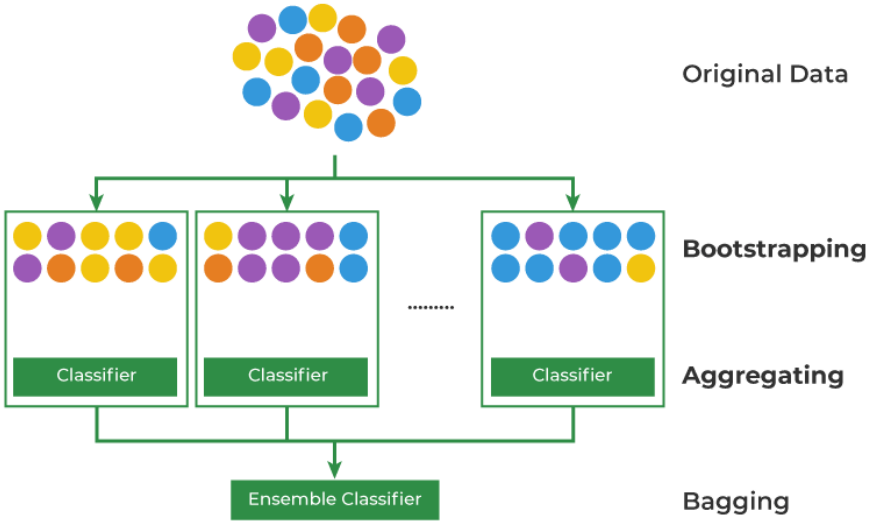
RandomForest

Bagging (bootstrap aggregation)

Training data set replacement 70-80%

Test (Validation) data set 30-20%



https://www.geeksforgeeks.org/

Two main components of the Random Forest algorithm (and other decision tree variants) are selection of features and the tree structure:

Hyperparameters

n_estimators
max_depth
min_samples_split
max_leaf_nodes

number of tress (ntree)
number of features to try (mtry)

↑ performance, accuracy

ntree = 100-500
mtry = total/3 or sqrt(total)

↑ computation resources

RAINBOWR

Linear / logistic regression
Additive, epistatic

Haplotype-based analysis
(without prior information)

Can control for several cofactors
- Relatedness (matric of covariance)
- Pop structure (Q matric from structure)
- Covariate factors, sex, age etc (phonotype table
